# Stein's method is a powerful technique for obtaining bounds of optimal rates in distributional approximations.

- Works for many target distributions: Normal, Poisson, ...
- Works in the presence of dependence.
- Applications include: molecular sequence analysis, permutation tests, statistical physics ...
- Some applications of the method require a coupling of  $Y_n$  to a  $Y'_n$  possessing certain inconvenient properties, e.g. boundedness.

Stein's method is a powerful technique for obtaining bounds of optimal rates in distributional approximations.

Introduction

Some unbounded couplings can be handled by showing that a certain configuration  $V_n$  reduced from the one that gives  $Y_n$ , conditioned on  $J_n$ , is the same as the original problem on a slightly smaller scale:

$$\mathcal{L}_{\theta}(V_n|J_n) = \mathcal{L}_{\psi_{n,\theta}}(Y_{n-L_n})$$

Based on ideas from Bolthausen (1985) for the Combinatorial Central Limit Theorem,  $A \in \mathbb{R}^{n \times n}, \pi \in S_n$ ,

$$Y = \sum_{i=1}^{n} a_{i,\pi(i)}$$

#### Examples: Graph and Occupancy Model

Erdős-Rényi graph: Let  $Y_n$  be the number of degree d vertices in the random graph with n vertices, where for each distinct pair of vertices u, v the indicators  $E_{\{u,v\}}$  of the existence of an edge between u and v are independent Bernoulli random variables with success probability  $\theta/(n-1)$ .

Occupancy: Let  $Y_n$  be the number of bins having d balls when distributing n balls over m urns. Species counting problem, and author attribution literature: how many words did Shakespeare know?

In both cases,  $Y_n$  is the sum of (globally) dependent variables.

Distance  $d(\mathcal{L}(W), \mathcal{L}(Z))$  obtained by Stein's method depends on class of functions to which test function *h* belongs.

1. Wasserstein distance

$$d_1(\mathcal{L}(W),\mathcal{L}(Z)) = \int_{-\infty}^{\infty} |F(x) - G(x)| dx,$$

consider *h* Lipschitz, satisfying  $|h(y) - h(x)| \le |y - x|$ .

2. Kolmogorov distance

$$d_{\infty}(\mathcal{L}(W),\mathcal{L}(Z)) = \sup_{z\in\mathbb{R}} |F(x) - G(x)|,$$

consider  $h(x) = \mathbf{1}(x \le z)$  indicator functions.

$$\begin{array}{c|ccc} \begin{array}{cccc} & \text{Equation and Coupling} & \begin{array}{cccc} & \text{Distances} & \text{Degree, Occupancy} & \begin{array}{cccc} & \text{Inductive Step} & \text{History} & \begin{array}{cccc} & \text{Cast} & \text{Directions} \\ & \circ & \circ & \circ \end{array} \end{array}$$

Wasserstein  $d_1$  distance easier to handle than Kolmogorov  $d_{\infty}$ . For instance, for  $d_1$  we have

$$|f'(w) - f'(w+t)| \le t ||f''||$$
 and  $||f''|| \le 2||h'||.$ 

For  $d_{\infty}$  test functions the solution f does not posses two derivatives, and h must be smoothed. Bothausen's inequality:

$$|f'(w) - f'(w+t)| \le |t| \left(1 + |w| + \frac{1}{\lambda} \int_0^1 \mathbb{1}_{[z,z+\lambda]}(w+ut) du\right)$$

where  $\lambda > 0$  is amount of smoothing performed on  $h(w) = \mathbf{1}(w \le z)$ .

Term in integral yields probability of small interval, not of 'moment' type, but easy to bound when coupling is bounded.

Degree, Occupancy

The coupling of  $Y_n$  and  $Y_n^s$  is not bounded. It is possible that the chosen vertex I had many edges, and all but d of them were then removed in order for I to attain degree d.

 $V_n$ : Removing I and all its incident edges leaves an Erdős-Rényi random graph on n-1 vertices.

 $J_n$ : The vertex I and its degree D(I) are independent of the reduced graph, yet

$$|Y_n^s - Y_n| \le 1 + |d - D(I)|.$$

Similarly, form a configuration where a randomly selected urn I contains exactly d balls by removing or adding balls uniformly from all other urns. This coupling has the same unboundedness property as the previous.

Inductive step: Removing urn I and it contents of M(I) balls leaves occupancy problem with n - M(I) balls and m - 1 urns.

The multinomial occupancy problem is substantially more difficult than graph degree. The number of balls in the one, unlike the number of edges in the other, must remain fixed: compare removing a vertex connected to all other vertices, and removing an urn containing all balls.

Inductive method: Applied for the graph and occupancy situations obtains the correct rate for all  $d \in \{0, 1, ..., \}$ .

### Cast of Main Characters: Occupancy

- 1.  $Y_n$ : How many of the *m* urns contain *d* balls when *n* balls are uniformly distributed.
- 2.  $Y_n^s$ : Number of *m* urns with *d* balls after adding or removing balls from urn  $I_n$ , randomly selected, so that it has occupancy *d*.
- 3.  $J_n$ : Identity  $I_n$  of selected urn and its occupancy  $M_n(I_n)$ .
- 4.  $K_n$ : Bound  $1 + |M_n(I_n) d|$  the absolute number  $|Y_n^s Y_n|$  of urns whose occupancy is affected by adding or removing balls when forming  $Y_n^s$ .
- 5.  $V_n$ : Number of urns other than  $I_n$  with occupancy d.

$$\mathcal{L}_m(V_n|J_n) = \mathcal{L}_{m-1}(Y_{n-M_n(J_n)})$$

Presently only the size bias coupling is handled. The inductive method can also be used for exchangeable pairs, and the more general *G*-coupling framework of Chen and Roellin, as well as with the zero bias coupling.

Should yield results on counts more general than number of urns with exactly d balls, eg. numbers of urns with more than d balls, or number of balls in excess of d summed over all urns.

Also can be applied to more general statistics on the Erdős-Rényi graph.
